Title :- Clinkt case file

Introduction:-

Clinkt is an investigation into a critical issue faced by customers during the online shopping journey. Some customers reported that products appeared to be available while browsing, but became unavailable or disappeared when they reached the checkout stage. This inconsistency can create frustration, reduce customer trust, and potentially result in lost sales for the business.

The purpose of this project is to investigate the underlying reasons for this issue using the available customer, product, transaction, customer interaction, and inventory data. Rather than assuming a single cause, we analyze the relationships between these datasets to identify the most significant patterns and determine which factors genuinely contribute to the problem.

Our investigation focuses on identifying what is happening, why it is happening, how strongly the data supports our findings, and what patterns can be ruled out. The findings will then be used to estimate the potential business impact and develop practical recommendations for Clinkt.

Based on the investigation, we propose a technology-driven solution in the form of a application that can provide customers with more accurate and timely product availability information. The solution aims to reduce the gap between product browsing and checkout, improve the reliability of

inventory information, and create a smoother and more trustworthy shopping experience.

Project Objective:-

The primary objective of this project is to identify the root causes of product availability issues, support the conclusions with data-driven evidence, quantify their potential business impact, and recommend an effective solution for Clinkt.

Problem Statement:-

Some customers face a frustrating issue while shopping online: products that appear to be available while browsing may become unavailable or disappear by the time the customer reaches the checkout page. This can happen because of changing inventory, delayed stock updates, or poor synchronization between the product catalog and checkout system.

This issue can lead to failed purchases, wasted time, customer frustration, and a poor shopping experience. It can also reduce customer trust in the platform.

Proposed Solution:-

To solve this problem, we are developing **Clinkt**, a gapapplication designed to provide customers with more accurate and up-to-date product availability information.

Clinkt aims to keep product availability synchronized with inventory and provide timely updates to users. Before and during the checkout process, the system can verify whether the selected product is still available, helping customers avoid reaching checkout only to discover that the product is no longer in stock.

The goal of Clinkt is to create a smoother, more reliable, and transparent online shopping experience for customers while helping businesses manage and communicate their inventory more effectively.
